

Errata to
“The Universality of Thomas L. Etter’s Three-Place Identity:
A Formal Proof and Its Significance”

James Bowery

June 17, 2026

The following corrections result from checking the paper’s claims against Etter’s primary sources and the accompanying Lean 4 development. They concern Appendices A and B (the Stereo and RCV constructions) and the Lean modules that formalize them. *The main body of the paper is unaffected.* Definitions D1 and D2, Theorems 4.1–4.3, and their mechanization (the round-trip theorem of §5) are a faithful transcription of Etter’s construction in *Three-place Identity* [E3] and stand unchanged; so does the paper’s use of “universality” in the sense of expressive adequacy / relative interpretability, which is Etter’s own rigorous notion of an open system and is the correct claim.

Erratum 1 — The derived membership of Appendices A and B is not a ZF membership

Location. Definition A.2; the RCV membership of §B.3.

As published. $y \in' x \iff \neg(E_1(y, x) \wedge E_2(y, x))$ (A.2), and $y \in_{\text{RCV}} x \iff \neg(R(y, x) \wedge C(y, x))$ (§B.3), asserted to satisfy / support the axioms of ZF set theory.

Correction. Because E_1, E_2 (resp. R, C) are equivalence relations, hence symmetric, each defined relation is *symmetric*:

$$y \in' x \iff x \in' y.$$

ZF membership is not symmetric—e.g. $\emptyset \in \{\emptyset\}$ but $\{\emptyset\} \notin \emptyset$ —so neither relation can satisfy Extensionality (or Foundation beyond the trivial $x \notin' x$). Consequently the claims in §A.2–A.3 that this membership yields “full ZF set theory” and in §B.3 that the RCV definition “satisfies the axioms of ZF set theory” are **withdrawn**. Equivalently, non-membership $E_1 \wedge E_2$ is the intersection of two equivalence relations and is therefore itself an equivalence relation—a fact Etter states directly (“only conjunction creates equalities out of equalities”, [E5]).

Separately, the ordered-pair encoding in §A.3 uses a distinct “link” construction that is *not* derivable from the A.2 membership; the two are independent and should not be presented as a single mechanism.

Erratum 2 — Provenance, and the correct RCV construction

As published. The intersection-style definitions above are presented as Etter’s stereo / RCV membership.

Correction. These formulas are the present author’s reconstructions; they do not occur in Etter’s surviving papers. Etter’s RCV→ZF membership is the *cell construction* of *The Expressive Power of Equality* [E1]: a cell is an ordered triple $\langle x, y, n \rangle$ with $x \varepsilon y$ and $n \in \{1, 2\}$; its value is

$\text{Val}(\langle x, y, n \rangle) = x$ if $n=1$, else y ; the predicates R, C, V are equalities *on cells* (same row, same column, same value), with V taken as identity; and membership is recovered from R, C, V alone by

$$\begin{aligned}\text{First}(c) &\iff \forall d \exists e (V(e=d) \wedge C(e=c)), \\ cEd &\iff \exists e, f (R(e=f) \wedge \text{First}(e) \wedge V(c=e) \wedge \neg \text{First}(f) \wedge V(d=f)).\end{aligned}$$

Appendix B should cite [E1] and use this construction. The argument-asymmetry supplied by $\text{First}/\neg\text{First}$ is precisely what the symmetric intersection formula of Erratum 1 lacks.

What stands. D1, D2, Theorems 4.1–4.3, and the *statements* of the stereo and RCV theorems are Etter’s and are transcribed faithfully.

Erratum 3 — Status of the appendix theorems (supersedes any “unproven” characterization)

Correction. The three-equality result—Theorem B.4, that ZF is constructively definable in an RCV language—is not merely asserted. It is proved in full in Etter’s *The Expressive Power of Equality* [E1] by the cell construction above, which also yields the pairing direction (B.5). The only genuinely incomplete item is the *two-equality* “Stereo Equality Theorem” of Appendix A: its complete proof was to appear in Etter’s *Membership and Identity* [E2], which survives only as an unfinished draft (so noted therein by R. Shoup), with a partial link construction sketched in *Three-place Identity* [E3, fn. 5]. Any “stated without proof” caveat therefore attaches to the two-equality claim only, not to the three-equality RCV result.

Erratum 4 — The Lean formalization of the appendices

Location. The modules `Stereo.lean` and `RCV.lean` accompanying Appendices A and B.

As published. The paper presents a Lean 4 mechanization of the development.

Correction. These two modules do not certify the appendices’ claims. They define `StereoMem y x` := $\neg(E_1 y x \wedge E_2 y x)$ and `Mem_RCV` by projecting R, C onto it (with V unused), and prove only: `stereo_irreflexivity` ($x \notin x$, trivial), `perfect_link_is_link` (definitional), and `link_determines_x` (partial first-component uniqueness). Every such theorem is true, but (i) the membership predicate and the link predicate are never related by any theorem; (ii) no ZF axiom beyond the irreflexivity sliver is established; (iii) the *symmetry* of the defined membership—the property that refutes it as a ZF membership (Erratum 1)—is never stated; and (iv) Etter’s cell apparatus (cells, Val , First , Theorems 1–2 of [E1]) is absent. The modules therefore formalize the incorrect intersection formula and verify only disconnected fragments; they should not be cited as evidence for Appendix B. A faithful mechanization would state, as a top-level goal the kernel must discharge, that the constructed membership is the membership of a ZF model—not merely a list of necessary lemmas. *The main-body module mechanizing Theorem 4.2 (the round-trip) is unaffected and stands.*

Left unchanged (to prevent over-correction)

- “Universality”/“Universality Theorem” and the abstract’s claim of expressive adequacy: Etter’s own rigorous notion of an open/universal system (relative interpretability). Correct; no change.
- Definitions D1, D2 and Theorems 4.1–4.3, with the round-trip Lean proof: faithful and correct.

- The proof of Theorem A.3 (Stereo Irreflexivity): valid *for* Definition A.2. The definition, not the derivation, is at issue in Erratum 1.

Net effect. These corrections *raise* the standing of the underlying program: Etter’s three-equality $\text{RCV} \rightarrow \text{ZF}$ result is complete and correct [E1]. The paper’s appendices substituted a symmetric—hence non-ZF—summary, and a Lean development that certifies only fragments of it, for a proof that already exists and should be cited.
